## BEE QUESTION PAPER SOLUTION

## (CBCGS DEC 16)

## Q1] a) State Maximum power Transfer Theorem

Solution:-
It states that 'The maximum power is delivered from a source to a load when the load resistance is equal to the source resistance.'

The maximum power will be transferred to the load when load resistance is equal to the source resistance.

## Q1] b)Derive the formula to convert a delta circuit into an equivalent star(4)

Solution:-

(a)

(b)

Referring to delta network shown,
The resistance between terminal 1 and $2=R_{C} \|\left(R_{A}+R_{B}\right)$
$=\frac{R_{C}\left(R_{A}+R_{B}\right)}{R_{A}+R_{B}+R_{C}}$ $\qquad$

Referring to the star network shown above , the resistance between terminals 1 and $2=$ $R_{1}+R_{2}$ $\qquad$ (2)

Since the two networks are electrically equivalent.
$R_{1}+R_{2}=\frac{R_{C}\left(R_{A}+R_{B}\right)}{R_{A}+R_{B}+R_{C}}$ $\qquad$
Similarly, $R_{2}+R_{3}=\frac{R_{A}\left(R_{B}+R_{C}\right)}{R_{A}+R_{B}+R_{C}}$
And $R_{1}+R_{3}=\frac{R_{B}\left(R_{A}+R_{C}\right)}{R_{A}+R_{B}+R_{C}}$
Subtracting Eq. (4) from Eq. (3)
$R_{1}-R_{3}=\frac{R_{B} R_{C}-R_{A} R_{B}}{R_{A}+R_{B}+R_{C}}$
Adding Eq.(6) and Eq. (5)
$R_{1}=\frac{R_{B} R_{C}}{R_{A}+R_{B}+R_{C}}$
Similarly, $\quad R_{2}=\frac{R_{A} R_{C}}{R_{A}+R_{B}+R_{C}}$
$R_{3}=\frac{R_{A} R_{B}}{R_{A}+R_{B}+R_{C}}$
Thus, star resistor connected to a terminal is equal to the product of the two delta resistors connected to the same terminal divided by the sum of the delta resistor.

## Q1] c) Define Average value and RMS value of an alternating quantity

Solution:-

1. AVERAGE VALUE.

The average value of an alternating quantity is defined as the arithmetic means of all the values over one complete cycle.

In case of a symmetrical alternating waveform the average value over a complete cycle is zero. Hence, in such a case the average value is obtained over half the cycle only.

The average value of any current (I) is given by,
$I_{\text {avg }}=\frac{i_{1}+i_{2} \ldots \ldots \ldots .+i_{n}}{m}$
The average value of any current $\mathrm{i}(\mathrm{t})$ over the specified interval $t_{1}$ and $t_{2}$ is expressed mathematically as,
$I_{\text {avg }}=\frac{1}{t_{2}-t_{1}} \int_{t_{1}}^{t_{2}} i(t) d t$
2. RMS VALUE.

The RMS value of the alternating current can be represented as follows:-
$I_{r m s}=\sqrt{\frac{i_{1}^{2}+i_{2}^{2} \ldots \ldots \ldots .+i_{m}^{2}}{m}}=\sqrt{\text { mean value of }(i)^{2}}$
The RMS value of any current $\mathrm{i}(\mathrm{t})$ over the specified interval $t_{1}$ to $t_{2}$ is expressed mathematically as,
$I_{r m s}=\sqrt{\frac{1}{t_{2}-t_{1}} \int_{t_{1}}^{t_{2}} i(t) d t}$
The RMS value of an alternating current is of considerable importance in practice because the ammeters and voltmeters record the rms value of alternating current and voltage respectively.

## Q1] d) Prove that power in a 3-phase delta connected system is 3 times that of a star connected system

Solution:-
Let a balanced load be connected in star having impedance per phase as $Z_{p h}$.
For a star-connected load
$V_{p h}=\frac{V_{L}}{\sqrt{3}}$
$I_{p h}=\frac{V_{p h}}{Z_{p h}}=\frac{V_{L}}{\sqrt{3} Z_{p h}} \quad \Rightarrow \quad I_{p h}=I_{L}=\frac{V_{L}}{\sqrt{3} Z_{p h}}$
Now, $P_{Y}=\sqrt{3} V_{L} I_{L} \cos \varphi=\sqrt{3} \times V_{L} \times \frac{V_{L}}{\sqrt{3} Z_{p h}} \times \cos \varphi=\frac{V_{L}^{2}}{z_{p h}} \cos \varphi$
For a delta-connected load
$V_{p h}=V_{L}$
$I_{p h}=\frac{V_{p h}}{Z_{p h}}=\frac{V_{L}}{Z_{p h}} \quad \Rightarrow \quad I_{p h}=\sqrt{3} I_{L}=\sqrt{3} \frac{V_{L}}{Z_{p h}}$
Now, $P_{\Delta}=\sqrt{3} V_{L} I_{L} \cos \varphi=\sqrt{3} \times V_{L} \times \sqrt{3} \frac{V_{L}}{z_{p h}} \times \cos \varphi=3 \frac{V_{L}^{2}}{Z_{p h}} \cos \varphi=3 P_{Y}$
$\boldsymbol{P}_{\boldsymbol{Y}}=\frac{1}{3} \boldsymbol{P}_{\Delta}$
Thus, power consumed by a balanced star-connected load is one third of that in the case of delta-connected load.

## Q1] e) Explain the working principle of a single phase transformer

Solution:-
When an alternating voltage $V_{1}$ is applied to a primary winding, an alternating current $I_{1}$ flows in it producing an alternating flux in the core. As per Faraday's laws of electromagnetic induction, an emf $e_{1}$ is induced in the primary winding.

(a)

(b)

Fig. 6.5 Working principle of a transformer
$e_{1}=-N_{1} \frac{d \varphi}{d t}$
Where $N_{1}$ is the number of turns in the primary winding. The induced emf in the primary winding is nearly equal and opposite to the applied voltage $V_{1}$.

Assuming leakage flux to be negligible, almost the flux produced in primary winding links with the secondary winding. Hence, an emf $e_{2}$ is induced in the secondary winding.
$e_{2}=-N_{2} \frac{d \varphi}{d t}$
Where $N_{2}$ is the number of turns in the secondary winding. If the secondary circuit is closed through the load, a current $I_{2}$ flows in he secondary winding. Thus energy is transferred from the primary winding to the secondary winding.

## Q1] f) What is the use of commutator in a DC machine.

Solution:-
A commutator is used for collecting current from the armature conductors. It is made of a number of wedge- shaped segments of copper. These segment are insulated from each other by thin layers of mica. Each commutator segment is connected to the armature conductor. The commutator converts the ac current induced in the armature conductors into unidirectional current across the brushes .

Q2] a) Obtain current through $1 \Omega$ resistance by using Super position theorem, in given diagram.

Solution:-

1. When 10 V is active :-

Applying mesh analysis:-
Mesh 1
$-10+3 I_{1}+2\left(I_{1}-I_{3}\right)=0$
$3 I_{1}+2 I_{1}-2 I_{3}=10$
$5 I_{1}-2 I_{3}=10$

Mesh 2
$-10+2\left(I_{2}-I_{3}\right)+2 I_{2}=0$
$2 I_{2}-2 I_{3}+2 I_{2}=10$
$4 I_{2}-2 I_{3}=10$

## Mesh 3

$-2\left(I_{3}-I_{2}\right)-2\left(I_{3}-I_{1}\right)+I_{3}=0$
$-2 I_{3}+2 I_{2}-2 I_{3}+2 I_{1}+I_{3}=0$
$2 I_{1}+2 I_{2}-3 I_{3}=0$
From equation (1), (2) and (3), we get
$\mathbf{I}^{\prime}=7.5 \downarrow \mathrm{~A}$
2. When 1 A is active :-

Modified circuit
$\mathbf{I}^{\prime \prime}=\mathbf{1} \uparrow \mathbf{A}$

$\mathrm{I}(1 \Omega)=-7.5+1=-6.5$
$I(1 \Omega)=6.5 \downarrow A$
Current passing through $1 \Omega$ is 6.5 A

Q2] b) A coil is connected across a non-inductive resistor of $120 \Omega$. When a $240 \mathrm{~V}, 50 \mathrm{~Hz}$ supply is applied to this circuit the coil draws a current of 5 A and the total current is 6A. Determine the power and the power factor of (i) the coil. (ii) the whole circuit .

Q3] a) Obtain Norton's equivalent circuit of the network, across the terminal $A$ and $B$

Solution:-

1. Calculation of $I_{N}$

Replacing the $3 \Omega$ by a short circuit
Applying KVL to mesh 1
$-15+8 I_{1}+16\left(I_{1}-I_{2}\right)+2 I_{1}=0$
$8 I_{1}+16 I_{1}-16 I_{2}+2 I_{1}=15$
$26 I_{1}-16 I_{2}=15$

Applying KVL to mesh 2
$5+10\left(I_{2}-I_{3}\right)+2 I_{2}+16\left(I_{2}-I_{1}\right)=0$
$10 I_{2}-10 I_{3}+2 I_{2}+16 I_{2}-16 I_{1}=-5$
$-16 I_{1}+28 I_{2}-10 I_{3}=-5$

Applying KVL to mesh 3
$-5+10\left(I_{3}-I_{2}\right)+2 I_{3}=0$
$10 I_{3}-10 I_{2}+2 I_{3}=5$
$-10 I_{2}+12 I_{3}=5$
From (1), (2) and (3) we get,
$I_{1}=1.103 \mathrm{~A}$
$I_{2}=0.855 \mathrm{~A}$
$I_{3}=1.129 \mathrm{~A}$
$I_{N}=1.129 \mathrm{~A}$
2. Calculation of $R_{N}$

$2 \Omega$

Replacing voltage sources by short circuits
$8 \Omega+2 \Omega=10 \Omega$
$(10 \Omega|\mid 16 \Omega)=6.1533 \Omega$
$6.15 \Omega+2 \Omega=8.15 \Omega$
$8.15 \Omega|\mid 10 \Omega=4.49 \Omega$
$4.49 \Omega|\mid 2 \Omega=6.46 \Omega$

$$
R_{N}=6.49 \Omega
$$

3. Norton's Equivalent circuit.

Q3] b) A series RLC circuit if $\omega_{o}$ is the resonant frequency $\omega_{1}$ and $\omega_{2}$ are the half power frequencies, prove that $\omega_{o}=\sqrt{\omega_{1} \omega_{2}}$

## Solution:-

The impedance is purely resistive i.e. the LC series combination acts like a short circuit and the entire voltage is across R. voltage and current are in phase and therefore the power factor is unity. The magnitude of the transfer function is minimum. The inductor voltage and capacitor voltage can be much more than the source voltage. The frequency response of the circuit's current magnitude:
$I=|I|=\frac{V_{m}}{\sqrt{R^{2}+(\omega L-1 / \omega C)^{2}}}$
The average power dissipated by the RLC circuit.
$P(\omega)=\frac{1}{2} I^{2} R$
The highest power dissipated happens at the resonance when current pak of $I=\frac{V_{m}}{R}$
$P\left(\omega_{o}\right)=\frac{1}{2} \frac{V_{m}}{R}$
Lets assume that half power is dissipated at frequencies of $\omega_{1}$ and $\omega_{2}$ :
$P\left(\omega_{1}\right)=P\left(\omega_{2}\right)=\frac{\left(V_{m} / \sqrt{2}\right)^{2}}{2 R}=\frac{V_{m}^{2}}{4 R}$
The half-power frequencies can be obtained by setting $Z$ equal to $\sqrt{2} R$

$$
\begin{aligned}
& \sqrt{2} R=\sqrt{R^{2}+\left(\omega L-\frac{1}{\omega C}\right)^{2}} \\
& \omega_{1}=-\frac{R}{2 L} \sqrt{\left(\frac{R}{2 L}\right)^{2}+\frac{1}{L C}} \\
& \omega_{2}=\frac{R}{2 L} \sqrt{\left(\frac{R}{2 L}\right)^{2}+\frac{1}{L C}} \\
& \omega_{o}=\sqrt{\omega_{1} \omega_{2}} \quad \quad . . . . . . .(\text { hence proved })
\end{aligned}
$$

## Q3] c) Derive the equivalent circuit of a 1- phase transformer

## Solution:-

Equivalent circuit diagram of a transformer is basically a diagram which can be resolved into an equivalent circuit in which the resistance and leakage reactance of the transformer are imagined to be external to the winding.

The equivalent circuit diagram of transformer is given below:-

(fig-1)
Where,
$\mathrm{R}_{1}=$ Primary Winding Resistance.
$\mathrm{R}_{2}=$ Secondary winding Resistance.
$\mathrm{I}_{0}=$ No-load current.
$I_{\mu}=$ Magnetizing Component,
$I_{w}=$ Working Component,
This $I_{\mu} \& I_{w}$ are connected in parallel across the primary circuit. The value of $E_{1}$ (Primary e.m.f ) is obtained by subtracting vectorially $I_{1} Z_{1}$ from $V_{1}$. The value of $X_{0}=E_{1} / I_{0}$ and $R_{0}=$ $E_{1} / I_{w}$. We know that the relation of $E_{1}$ and $E_{2}$ is $E_{2} / E_{1}=N_{2} / N_{1}=K$, ( transformation Ratio)

From the equivalent circuit , we can easily calculate the total impedance of to transfer voltage, current, and impedance either to the primary or the secondary.

The secondary circuit is shown in fig-1. and its equivalent primary value is shown in fig-2

(fig-2)
The total equivalent circuit of the transformer is obtained by adding in the primary impedance as shown in - Fig-3

(fig-3)
And It can be simplified the terminals shown in fig - 4 \& further simplify the equivalent circuit is shown in fig- 5

At last, the circuit is simplified by omitting $l_{0}$ altogether as shown in fig- 5 .

(fig-5)

Q4] a) Obtain current through $15 \Omega$ resistance by nodal analysis. Take reference node as marked.

Solution:-
Applying KCL at node 1
$\frac{V_{1}-V_{2}}{20}+\frac{V_{1}-120}{15}+V_{1}-45-V_{3}=0$
$\frac{V_{1}}{20}-\frac{V_{2}}{20}+\frac{V_{1}}{15}-\frac{120}{15}+V_{1}-V_{3}=45$
$V_{1}\left(\frac{1}{20}+\frac{1}{15}+1\right)-V_{2}\left(\frac{1}{20}\right)-V_{3}=45+\frac{120}{15}$
$1.116 V_{1}-0.05 V_{2}-V_{3}=53$

Applying KCL at node 2

$$
\left(\frac{V_{2}-V_{1}}{20}\right)+\frac{V_{2}}{5}+\frac{V_{2}-V_{3}}{10}=0
$$

$V_{1}\left(-\frac{1}{20}\right)-V_{2}\left(\frac{1}{20}+\frac{1}{5}+\frac{1}{10}\right)-V_{3}\left(-\frac{1}{10}\right)=0$
$-0.05 V_{1}+0.35 V_{2}-0.1 V_{3}=0$

Applying KCL at node 3
$\left(\frac{V_{3}-V_{2}}{10}\right)+\left(\frac{V_{3}-20}{5}\right)+\left(V_{3}-(-45)-V_{1}\right)=0$
$-V_{1}+V_{2}\left(\frac{-1}{10}\right)+V_{3}\left(\frac{1}{10}+\frac{1}{5}+1\right)-\frac{20}{5}+45=0$
$-V_{1}-0.1 V_{2}+1.3 V_{3}=-41$
From (1) , (2) and (3) we get,
$V_{1}=67.70 \mathrm{~V} \quad V_{2}=15.89 \mathrm{~V} \quad V_{3}=21.76 \mathrm{~V}$
Current through $15 \Omega$ resistor :-
Applying KCL :-
$I=\frac{V_{1}-120}{15}=\frac{67.70-120}{15}=-3.48 \mathrm{~A}$
$I=3.48(\leftarrow) \mathrm{A}$

Q4] b) In a balanced 3 phase, star connected system, a wattmeter is connected with its current coil in series with $Y$ line pressure coil between $Y$ and $R$ lines. Draw a neat circuit diagram showing the above wattmeter connection. Assuming a lagging power factor, draw the corresponding phasor diagram and derive the wattmeter reading in terms of line voltage, phase current and power factor.

## Solution:-

three wattmeter are inserted in each of the three phase of the load whether star connected or delta connected. Each wattmeter will measure the power consumed in each phase.

For balanced load, $W_{1}=W_{2}=W_{3}$
For unbalanced load, $W_{1} \neq W_{2} \neq W_{3}$
Total power $\mathrm{P}=, W_{1}+W_{2}+W_{3}$

Let $V_{R N}, V_{Y N}$ and $V_{B N}$ be the three phase voltages, $I_{R}, I_{Y}$ and $I_{B}$ be the phase currents. The phase currents will lag behind their respective phase voltage by angle

Current through current coil of $W_{1}=I_{R}$
Voltages across voltage coil of $W_{1}=V_{R B}=V_{R N}+V_{N B}=V_{R N}-V_{B N}$
$W_{1}=V_{R B} I_{R} \cos (30-\varphi)$
Current through current coil of $W_{2}=I_{Y}$
Voltage across voltage coil of $W_{2}=V_{Y B}=V_{Y N}+V_{N B}=V_{Y N}-V_{B N}$
$W_{2}=V_{Y B} I_{Y} \cos (30+\varphi)$
$I_{R}=I_{Y}=I_{B}$
$W_{1}=V_{R B} I_{R} \cos (30-\varphi)$
$W_{2}=V_{Y B} I_{Y} \cos (30+\varphi)$
$W_{1}+W_{2}=V_{L} I_{L}[\cos (30+\varphi)+\cos (30-\varphi)]=\sqrt{3} V_{L} I_{L} \cos \varphi$
In terms of phase current,
$\mathrm{P}=3 V_{p h} I_{p h} \cos \varphi$

Solution:-

Current through mesh 2 is $\mathrm{I}=1 \mathrm{~A}$.
$I_{2}=1 \mathrm{~A}$
Applying mesh analysis:-
Mesh 1
$-100+10 I_{1}+10\left(I_{1}-1\right)+60\left(I_{1}-I_{3}\right)=0$
$10 I_{1}+10 I_{1}+60 I_{1}-60 I_{3}=110$
$80 I_{1}-60 I_{3}=110$

Mesh 3
$-60\left(I_{3}-I_{1}\right)-20\left(I_{3}-1\right)+50=0$
$-60 I_{3}+60 I_{1}-20 I_{3}+20+50=0$
$-60 I_{1}+80 I_{3}=70$
$I_{1}=4.64 \mathrm{~A} \quad I_{3}=4.35 \mathrm{~A}$
Current through $60 \Omega$ is $=I_{1}-I_{3}=4.64-4.35=0.29 \mathrm{~A}$

$$
\mathrm{I}(60 \Omega)=0.29 \mathrm{~A}
$$

## Q5] b) Develop the phasor diagram of a single transformer supplying to a resistive load.

## Solution:-

If the load is resistive or power factor is unity, the voltage V2 and I2 are in phase. Steps to draw the phasor diagram are,

1. Consider flux $\Phi$ as reference
2. E 1 lags $\Phi$ by 90 . Reverse E 1 to get -E1.
3. E1 and E2 are inphase
4. Assume V2 in a particular direction
5. 12 is in phase with V 2 .
6. Add I 2 R 2 and I 2 X 2 to to get E 2 .
7. Reverse 12 to get 12 '.
8. Add lo and I2' to get I1.
9. Add I1 R1 and to -E1 to get V1.

Angle between V1 and I1 is $\Phi 1$ and $\cos \Phi 1$ is primary power factor. Remember that I1X1 leads 11 direction by 90 and $\mathrm{I} 2 \times 2$ leads I 2 by 90 as current through inductance lags voltage across inductance by 90 . The phasor diagram is shown in the Fig. shown below

## Q5] c) Derive the emf equation of a DC generator

## Solution:-

Let $\varphi=$ flux per pole in Webbers .
$Z=$ Total number of armature conductors.
$\mathrm{N}=$ Speed of the armature in revolution per minute(rpm)
$\mathrm{P}=$ Number of poles.
$A=$ Number of parallel paths.
When the armature completes one revolution, each conductor cuts the magnetic flux. Therefore flux cut by one conductor in one revolution of the armature.

$$
\begin{aligned}
& =\text { flux per pole } \times \text { number of poles } \\
& =\varphi \mathrm{p} \text { Webbers }
\end{aligned}
$$

Time taken to complete one revolution $=\frac{60}{N}$ seconds
Hence, average emf induced in one conductor $=\frac{\text { flux cut }}{\text { time taken }}$

$$
=\quad \frac{\varphi P}{60 / N}=\frac{\varphi P N}{60} \text { volts }
$$

Induced emf (E) = Resultant emf per parallel path

$$
=\text { Average emf per conductor } \times \text { Number of conductors in series per }
$$

parallel paths
Induced emf(E) $=\frac{\varphi P N}{60} \times \frac{Z}{A}=\frac{\varphi Z N}{60} \frac{P}{A}$ volts
In case of a DC generator, this emf is called generator emf(Eg). In case of a DC motor , this emf apposes the applied emf and hence, it is called back emf (Eg)

Q6] a) A resistor and a pure reactance are connected in series across a 150 V ac supply. When the frequency is 40 Hz , the circuit draws 5 A . When the frequency is increased to 50 Hz , the circuit draws 6A. find the value of resistance and the element value of the reactance. Also find the power drawn in the second case.

## Solution:-

$V=150 \mathrm{~V}$
$f_{1}=40 \mathrm{~Hz}$
$f_{2}=50 \mathrm{~Hz}$
$I_{1}=5 A$
$I_{2}=6 A$

1. Values of $R$ and $C$

For $f_{1}=40 \mathrm{~Hz}$
$Z_{1}=\frac{V}{I_{1}}=\frac{150}{5}=30 \Omega$
$Z_{1}=\sqrt{R^{2}+\left(\frac{1}{2 \pi f_{1} C}\right)^{2}}=\sqrt{R^{2}+\left(\frac{1}{80 \pi C}\right)^{2}}$
$R^{2}+\left(\frac{1}{80 \pi c}\right)^{2}=900$
For, $f_{2}=50 \mathrm{~Hz}$
$Z_{2}=\frac{V}{I_{2}}=\frac{150}{6}=25 \Omega$
$Z_{2}=\sqrt{R^{2}+\left(\frac{1}{2 \pi f_{2} C}\right)^{2}}=\sqrt{R^{2}+\left(\frac{1}{100 \pi C}\right)^{2}}$
$R^{2}+\left(\frac{1}{100 \pi c}\right)^{2}=625 \Omega$
Solving equation (1) and (2),
$R=19.96 \Omega$
$C=69.4 \mu F$
2. Power drawn in the second case
$P_{2}=I_{2}^{2} R=(6)^{2} \times 19.96=718.56 \mathrm{~W}$

Q6] b) A single phase $10 \mathrm{KVA}, 500 \mathrm{~V} / 250 \mathrm{~V}, 50 \mathrm{~Hz}$ transformer has the following constants.

Resistance :primary = $\mathbf{0 . 2}$ ohms, secondary= $\mathbf{0 . 5}$ ohms
Reactance :primary $\mathbf{=} \mathbf{0 . 4}$ ohms, secondary $\mathbf{=} \mathbf{0 . 2}$ ohms
Resistance of equivalent exciting circuit w.r.t. primary = 1500 ohms
Reactance of equivalent exciting circuit w.r.t primary $=\mathbf{7 5 0}$ ohms
What will be the reading of the instrument placed in primary side when the transformer is connected for OC and SC test?

Solution:-
